

The document belongs to the record. *Not to the folder.*

Half of a company's documents are not created in the ERP. How they are uploaded from the form somebody is already in — with metadata the form already knows.

“Contracts/old”. Vendor: *renamed.*

The framework contract sat under “Vendors/M/Mueller GmbH/Contracts/old”. The vendor in the ERP had a different name by then. The contract was valid. Nobody found it.

A path holds until somebody *tidies up.*

The vendor has a number that does not change when it renames itself. The folder has a name that changes when somebody tidies. A document should hang on the first.

Where somebody *already is.*

Add file

in the ECM menu on vendor, order,
project

Drag and drop

from Explorer, from Outlook

PDF, Office, images, e-mail

.msg and .eml included

No folder

nobody names anything afterwards

The user *types nothing.*

- 01 Form data: vendor number, order, project — from the record
 - 02 Fixed value: account type, reference type — same per form
 - 03 Function: computed rather than read, via display method
 - 04 Upload and scan with separate mappings
-

From three. *Not from thirty.*

Per form you define which external document types are offered. On the vendor: contract, certificate, correspondence. File size and types are limited — so no video hangs on a vendor.

The contract hangs on the vendor.

Whatever it is called today.

The e-mail lands on the order.

From Outlook, one move.

No folder called “old”.

Because there is no folder.

A document belongs to *a record*.

FlexxStore — the ECM solution for Dynamics 365 — receives external documents from any form, with metadata from the record and document type from a list. Built by the Soluvine development team I have worked with since Damgaard.

External document types	freely definable, with metadata
30-day trial	no obligation
