

The paper knows *its record.*

The signed delivery note comes back in the evening. Who matches it to the order? How barcode and scan type turn a stack of paper into archived documents.

Sixty delivery notes. *One table.*

The next morning somebody scans them, reads each order number, renames each file. Two hours, every day. And when that person is absent, the stack sits.

A scan without a match is *a file.*

Scanning is solved. Matching is not: turning a PDF into an entry that hangs on the right order. The paper knows where it belongs — the number is on it. It just cannot tell anybody.

Printed. Scanned. *Found.*

Created by batch	for all records that meet a condition
First page	FlexxStore reads it and finds the order
Retroactive	scan before barcode waits and is matched
One document type per scan type	delivery note is not inspection report

The number that is already *on it.*

The supplier sticks on its own labels. An existing barcode is registered in Dynamics 365 and linked to the record. Via REST from the scanning provider: file, barcode ID, optionally scan type. Nothing more.

Two points for *one person*.

-
- 01 Scan type unknown: ECM dashboard, administrator assigns
 - 02 No barcode found: scan dashboard, matched by hand
 - 03 Without the permission, the scan type is not even visible
 - 04 Sixty become two that somebody looks at
-

The delivery note hangs on the order.

Before anybody reads it.

Fifty-eight find their own way.

Two need help.

The stack does not sit when somebody is ill.

The scanner is never ill.

IN SHORT

Paper that knows its record *needs nobody.*

FlexxStore — the ECM solution for Dynamics 365 — matches scanned documents to their record automatically via barcode and scan type; the rest sits visibly in the scan dashboard. Built by the Soluvine development team I have worked with since Damgaard.

Barcode matching

printed, external or via REST

30-day trial

no obligation
