

An archive *fails quietly.*

Archiving is a background process, and background processes do not announce themselves. How the ECM dashboard gives every document a state — and what an archive has to prove in operation.

Three days. *No alarm.*

The viewer kept showing previews because the entries were there. The files did not arrive — a password had expired. Nobody noticed, because nothing turned red.

Nobody has to
think about it.
Nobody notices.

Everything in this series runs in the background.
That is its strength and its weakness. So it needs
a place where its state is shown — not a message
that may or may not arrive.

Every document. *One state.*

Indexed

entry there, file still missing

Waiting for transfer

file there, batch not yet

Archived

in the archive, with file

Error

with a reason: “check delivery”, not
“error 17”

Fix the cause. *Reset the status.*

The batch job retries on its own as long as the file is missing. Once the cause is fixed, “reset status” restarts the attempt — for one document or all with the same cause. Nobody re-archives three days by hand.

Two endpoints. *One export.*

-
- 01 REST “Add file”: document with document type and references
 - 02 REST “Scan file”: document with barcode ID, runs through matching
 - 03 Reference to external storage: index only
 - 04 Configuration via data management: test becomes template for production
-

Ten seconds of dashboard in the morning.

The night ran. Or not.

An error has a reason.

Not a number.

The second legal entity is an import.

Not busywork.

An archive proves itself *in operation*.

FlexxStore — the ECM solution for Dynamics 365 — gives every document a state, retries on its own, accepts documents via REST and exports its configuration as a template. Built by the Soluvine development team I have worked with since Damgaard.

ECM dashboard

states, retry, reset

30-day trial

no obligation
