

Four modes. One *decision*.

How fast data may enter the books is an operating decision, not a technical one.

Go-live and peak season in the *same gear.*

Automate everything on day one and you post errors in series. Approve every document by hand at peak and the interface backs up — while you wait for figures that arrived long ago.

For *starting out.*

Every step is triggered: check, approve, post.
Slow, but everyone sees what the system does.
The right mode for the first weeks with a new partner.

Instant — at low *volume*.

Message in, checked, posted. Tightly coupled and fast, as long as volumes stay small. At high volume it turns into waiting time at the interface.

Approval and posting *decoupled.*

Intake stays fast while the slow work runs in a batch — with priorities per interface and several threads in parallel. The usual mode in day-to-day operation.

Highest *throughput.*

Intake and processing are separate and several threads run in parallel. The partner gets an answer in milliseconds; the work follows. For companies taking thousands of messages a day at peak.

Go-live needs no rebuild.

Start manual, switch later — same installation.

Season is a setting.

Change the mode instead of the hardware or the process.

The interface stops holding you up.

Long work no longer runs inside the call with your partner.

IN SHORT

Speed is not a property. *It is a setting.*

FlexxLink — the integration platform for Dynamics 365 — offers four processing modes, from manual to parallel, with no rebuild in between. Built by the Soluvine development team I have worked with for 25 years. The modules in detail:
